

METHOD FOR LIGHTING AN INDUCTIVELY COUPLED PLASMA  
AT LOW PRESSURE

ABSTRACT OF THE DISCLOSURE

5 A method is described for lighting an inductive plasma in  
a plasma processing tool having a matching network, at  
pressures of about 20 mTorr and below. A matching condition  
for a capacitive plasma is determined, which then is used to  
define a match preset condition. When a plasma is started with  
the matching network in that preset condition, a capacitive  
plasma ignites and is maintained with a minimum of power.  
Excess power (power greater than that required to maintain the  
capacitive plasma) transfers the plasma to the inductive mode.  
The matching condition for the capacitive plasma may be  
determined by lighting a plasma, setting a power delivered  
thereto at not more than about 20 watts, and allowing the  
matching network to tune to the plasma. A capacitive plasma  
may be easily started at this preset condition. Current  
produced in the coil due to the excess power then causes the  
inductive plasma to light. The matching network changes from  
the preset matching condition to a matching condition under  
which the matching network is tuned to the inductive plasma.
